Spread Spectrum Techniques and Technology

Mark A. Sturza
3C Systems Company
“Spread spectrum is a means of transmission in which the signal occupies a bandwidth in excess of the minimum necessary to send the information: the band spread is accomplished by means of a code which is independent of the data, and synchronized reception with the code at the receive is used for de-spreading and subsequent data recovery.”
Advantages of Spread Spectrum

- Anti-jamming (A/J)
- Anti-interference (A/I)
- Low Probability of Intercept (LPI)
- Code Division Multiple Access (CDMA)
- Message Privacy
- High Resolution Ranging and Timing
Spread Spectrum Techniques and Technology

- Spectrum Spreading Techniques
- Processing Gain
- Jamming Margin
- System Comparison
- PN-Codes
- Gold Codes
- Other Codes
Spectrum Spreading Techniques

- Direct Sequence (DS)
- Frequency Hopping (FH)
- Time Hopping (TH)
- Hybrids

TH Waveform

- $T_W$ – pulse width (sec)
- $T_I$ – average pulse interval (sec)
- $\beta = \frac{T_W}{T_I}$ – duty cycle factor
TH Waveform (cont.)

• Typically $T_W$ is selected such that
  \[ \frac{B_D}{\beta} > \frac{1}{2T_W} \]

• Then
  \[ B_{SS} = \frac{BD}{\beta} \]

Given
- $T_W = 1$ msec, $T_I = 100$ msec, $B_D = 100$ Hz

Calculate
- $\beta = 0.01$, $B_{SS} = 10$ kHz

$\text{BSS} = 2 \times N \times R_C$

Given $R_C = 10 \text{ Mbps}$  $N = 50$

Calculate $B_{SS} = 1 \text{ GHz}$  $B_{IN} = 20 \text{ MHz}$

$R_C = \text{chip rate (bps)}$
Processing Gain

\[
PROCESSING \_ GAIN = \frac{\text{SPREAD} \_ \text{SPECTRUM} \_ \text{BANDWIDTH}}{\text{MINIMUM} \_ \text{INFORMATION} \_ \text{BANDWIDTH}}
\]

\[
G_P = \frac{B_{SS}}{B_D}
\]

Given

\[
\text{BSS} = 100 \text{ MHz} \quad \text{BD} = 2 \text{ kHz}
\]

Calculate

\[
\text{GP} = 50,000 \ (47 \text{ dB})
\]
DS Processing Gain

- $G_{P}^{DS} = \frac{\text{[Chip Rate]}}{\text{[Data Bit Rate]}} = \frac{R_{C}}{R_{D}}$
  - $= \frac{\text{[Data Bit Duration]}}{\text{[Chip Duration]}} = \frac{\tau_{D}}{\tau_{C}}$

Given

\[
\begin{align*}
R_{C} &= 10 \text{ Mbps} \\
R_{D} &= 5 \text{ kbps}
\end{align*}
\]

Calculate

\[
\begin{align*}
\tau_{C} &= 100 \text{ nsec} \\
\tau_{D} &= 200 \mu\text{sec}
\end{align*}
\]

$G_{P}^{DS} = 2,000 \ (33 \text{ dB})$
FH Processing Gain

- $G_p^{FH} = \text{Number of frequency choices} = N$

Given

\[
N = 20,000
\]

Calculate

\[
GPFH = 20,000 = 43 \text{ dB}
\]
TH Processing Gain

\[ GP_{TH} = \frac{1}{\text{DUTY CYCLE FACTOR}} = \frac{1}{\beta} = \frac{\text{Average Pulse Interval}}{\text{Pulse Width}} = \frac{T_I}{T_W} \]

Given

\[ \beta = 1.0\% \quad T_I = 100 \text{ msec} \quad T_W = 1 \text{ msec} \]

Calculate

\[ GP_{TH} ^ {TH} = 100 \ (20 \text{ dB}) \]
Hybrid Processing Gain

- The processing gain of a hybrid spread spectrum system is the product of the processing gains of the component systems assuming that orthogonality is maintained

\[ G_{P_{FH-DS}} = G_{P_{FH}} \times G_{P_{DS}} \]
\[ G_{P_{TH-DS}} = G_{P_{TH}} \times G_{P_{DS}} \]
\[ G_{P_{TH-FH}} = G_{P_{TH}} \times G_{P_{FH}} \]
\[ G_{P_{TH-FH-DS}} = G_{P_{TH}} \times G_{P_{FH}} \times G_{P_{DS}} \]
Hybrid Processing Gain (cont.)

- \( G_{\text{P}}^{\text{TH-FH-DS}} \, (\text{dB}) = G_{\text{P}}^{\text{TH}} \, (\text{dB}) + G_{\text{P}}^{\text{FH}} \, (\text{dB}) + G_{\text{P}}^{\text{DS}} \, (\text{dB}) \)

Given

\[
G_{\text{P}}^{\text{DS}} = 17 \, \text{dB} \quad G_{\text{P}}^{\text{FH}} = 25 \, \text{dB} \quad G_{\text{P}}^{\text{TH}} = 10 \, \text{dB}
\]

Calculate

\[
G_{\text{P}}^{\text{FH-DS}} = 42 \, \text{dB} \quad G_{\text{P}}^{\text{TH-DS}} = 27 \, \text{dB}
\]

\[
G_{\text{P}}^{\text{TH-FH}} = 35 \, \text{dB} \quad G_{\text{P}}^{\text{TH-FH-DS}} = 52 \, \text{dB}
\]
Hybrid Processing Gain (cont.)

Given

FH-DS SS System

\[ R_D = 1 \text{ kbps} \quad R_C = 1 \text{ Mbps} \quad N = 1,000 \]

Calculate

\[ G_P^{DS} = 30 \text{ dB} \quad G_P^{FH} = 30 \text{ dB} \quad G_P^{FH-DS} = 60 \text{ dB} \]

\[ R_D = 1 \text{ kbps} \Rightarrow B_D = 2 \text{ kHz} \]

\[ G_P^{FH-DS} = 60 \text{ dB} \Rightarrow B_{SS} = 2 \text{ GHz} \]
**Jamming Margin**

\[ M_J = \frac{G_P}{(S/N)_{\text{REQ}} \times L} \]

- \( M_J \) – Jamming Margin
- \( G_P \) – Processing Gain
- \( (S/N)_{\text{REQ}} \) – minimum required output SNR
- \( L \) – system implementation loss

\[ M_J \text{ (dB)} = G_P \text{ (dB)} - (S/N)_{\text{REQ}} \text{ (dB)} - L \text{ (dB)} \]

Given \( G_P = 43 \text{ dB} \quad (S/N)_{\text{REQ}} = 10 \text{ dB} \quad L = 2 \text{ dB} \)

Calculate \( M_J = 31 \text{ dB} \)
Jamming Margin (cont.)

\[ S = E_B \times R_D \quad \text{&} \quad N = N_0 \Rightarrow R_D \times (S/N)_{\text{REQ}} = (E_b/N_0)_{\text{REQ}} \]

- \( E_b \) – energy per bit (W)
- \( N_0 \) – one-sided noise spectral density (W/Hz)
- \( R_D \) – data bit rate (bps)

\[ M_J \quad (\text{dB}) = G_P \quad (\text{dB}) - (E_b/N_0)_{\text{REQ}} \quad (\text{dB}) - L \quad (\text{dB}) \]

Given a FH SS system with FSK modulation and required BER of \( 10^{-5} \) \( \Rightarrow (E_b/N_0)_{\text{REQ}} = 13 \text{ dB} \) with \( G_P = 43 \text{ dB} \) & \( L = 2 \text{ dB} \)

Calculate \( M_J = 28 \text{ dB} \)
Jamming Margin - Coding

- Coding does not reduce the jamming margin of a SS system

\[ M_J = \frac{G_P}{[(E_b/N_0)_{REQ} \times L]} = \left(\frac{B_{SS}}{B_D}\right) \times \left(\frac{N_0}{E_b}\right) \times L \]

\[ E_B = \frac{E_S}{r} \quad B_D = B_S \times r \]

- \( E_S \) – energy per code symbol (W)
- \( B_S \) – code symbol bandwidth (Hz)
- \( r \) – code rate (data bit/code symbol)

\[ M_J = \left(\frac{B_{SS}}{B_S}\right) \times \left(\frac{N_0}{E_S}\right) \times L \]
### Jamming Margin – Coding (cont.)

**Given**

- DS SS system with PSK modulation
- $R_D = 1$ kbps, $R_C = 10$ Mbps, $L = 1$ dB, $BER = 10^{-5}$

**Calculate**

- $(E_b/N_0)_{REQ} = 10$ dB, $G_P = 40$ dB, $M_J = 29$ dB

**Encode the data with 4 code symbols per data bit, $r = \frac{1}{4}$**

**Calculate**

- $R_S = 4$ kbps, $G_P = 34$ dB, $(E_S/N_0)_{REQ} = 4$ dB, $M_J = 29$ dB
Processing Gain Vulnerability – Predictor Jammer

• A predictor jammer observes the SS signal and via computational capabilities breaks the PN-code. It uses this knowledge of the code to predict the PN-code choice made by the SS system and allocates its resources to jam that choice.

• The predictor jammer’s ability to break the PN-code is a function of the code type and not a function of the SS technique used.
Processing Gain Vulnerability – Follower Jammer

- A follower jammer observes the PN-code choice made by the SS system and allocates its resources to jam that choice.
- To be effective the follower jammer must determine the PN-code choice, generate the appropriate jamming signal, and deliver that jamming signal to the receiver prior to the receiver switching to the next PN-code choice.
Processing Gain Vulnerability – Follower Jammer (cont.)

• Even an infinitely fast follower jammer is totally ineffective if

\[
1 / R_{PN} \leq \left[ R_{NG_TJ} - R_{NG_TR} + R_{NG_JR} \right] / c
\]

- PRN – PN-code rate (bps)
- c – speed of light (3 x 10^8 m/s)
- \( R_{NG_TJ} \) – range from transmitter to jammer (m)
- \( R_{NG_TR} \) – range from transmitter to receiver (m)
- \( R_{NG_JR} \) – range from jammer to receiver (m)
Processing Gain Vulnerability – Follower Jammer (cont.)

Given

\[ \text{RNG}_{\text{TJ}} = 10 \text{ km} \quad \text{RNG}_{\text{TR}} = 10 \text{ km} \quad \text{RNG}_{\text{JR}} = 1 \text{ km} \]

Calculate

\[ \frac{1}{R_{\text{PN}}} \leq 3 \mu\text{sec} \]

The follower jammer is totally ineffective if \( R_{\text{PN}} \geq 300 \text{ kbps} \)

- In practice, follower jammers are significant threats to FH and TH SS systems, and insignificant to DS SS systems
Comparison – Processing Gain

- For given $B_{SS}$ and $B_D$

<table>
<thead>
<tr>
<th>SS Technique</th>
<th>Processing Gain</th>
<th>Relative Comparison</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
PN-Codes

- Pseudorandom noise (PRN) code sequences are deterministically generated but have properties similar to random sequences generated by sampling a white noise process.
- PN-code sequences have pseudo-randomness properties.
Pseudo-Randomness Properties

1) Over the sequence period, the number of 1’s and 0’s differs by at most 1

2) Over the sequence period, half the runs have length 1, one-fourth have length 2, one-eight have length 3, etc. For each of the run lengths there are equally many runs of 0 and of 1

3) The autocorrelation function, $R(M)$, is binary valued, equal to 1 if $M$ equals 0, and $-1/N$ otherwise

Where \{A_N\} is the sequence with period N

$$B_N = 1 - 2A_N$$

$$R(M) = \frac{1}{N} \sum_{n=1}^{N} B_n B_{n+M}$$
Simple Shift Register Generator

- A simple shift register generator (SSRG) is a shift register generator (SRG) in which all feedback signals are returned to a single input.
Maximal Length Sequences

- The sequence generated by an N-stage SSRG is a maximal length sequence if it has length $2N - 1$
- All N-tuples are contained in a maximal length sequence except the sequence of N zeros

<table>
<thead>
<tr>
<th>SSRG Stages</th>

</tr>
</tbody>
</table>
SSRG Properties

• To generate a maximal length sequence a SSRG must have an even number of taps
• If \{a\} and \{b\} are two output sequences of a SSRG then so is \{a\} + \{b\}
• If a maximal length SSRG sequence is added to a shift of itself then the resulting sequence is another shift of the original sequence
Maximal Length Sequence Properties

- Maximal length sequences have pseudorandomness properties
  - $2^{N-1}$ ones and $2^{N-1} - 1$ zeros
  - Balanced runs, except there is no run of N zeros
  - Binary valued autocorrelation function, equal to 1 if M equals 0 and $-1/N$ otherwise
The SSRG and its generating function are related as follows

SSRG:

Generating Function:

\[ G(X) = 1 + C_1 X + C_2 X^2 + C_3 X^3 + \cdots + C_{N-1} X^{N-1} + C_N X^N \]
Maximal Length Sequence Generating Functions

• If $2^N - 1$ is prime, then every irreducible polynomial of degree $N$ is a maximal length sequence generating function (MLSGF)
  – A polynomial is irreducible if it can not be factored

• If $2^N - 1$ is not prime, then every primitive irreducible polynomial of degree $N$ is a MLSGF
  – A polynomial of degree $N$ is primitive if and only if it divides $X^M - 1$ for no $M < 2^N - 1$

Reciprocal Generating Functions

• The reciprocal of a primitive polynomial is primitive
• The reciprocal of an irreducible polynomial is irreducible
• Hence the reciprocal of a MLSGF is another MLSGF
• The reciprocal of a polynomial of degree N is
  \[ R(X) = X^N \cdot G\left(\frac{1}{X}\right) \]

Given

\[ G(X) = 1 + X + X^3, \text{ a MLSGF} \]

Calculate

\[ R(X) = 1 + X^2 + X^3, \text{ another MLSGF} \]
<table>
<thead>

</table>
Gold Codes

• Let F(X) and G(X) be MLSGF’s of degree N whose cross correlation function, R(K), satisfies
  \[|R(K)| \leq \begin{cases} 
  \frac{2^{(N+1)/2} + 1}{2^{N-1}}, & \text{N odd} \\
  \frac{2^{(N+2)/2} + 1}{2^{N-1}}, & \text{N even, N \neq 0 mod 4}
  \end{cases}\]

• Then the product polynomial F(X) G(X) will generate 2N + 1 different sequences of period 2N – 1, the cross correlation of all pairs satisfying the above inequality

• These sequences form the Gold code family of order N
Gold Codes (cont.)

Given

\[ F(X) = X^6 + X + 1 \]
\[ G(X) = X^6 + X^5 + X^2 + X + 1 \]

Calculate

\[ F(X) \cdot G(X) = X^{12} + X^{11} + X^8 + X^6 + X^5 + X^3 + 1 \]

65 Gold codes of period 63

\[ |R(K)| \leq 17 / 63 \text{ (-11 dB)} \]
Gold Codes (cont.)

\[ F(X) = X^6 + X + 1 \]
\[ G(X) = X^6 + X^5 + X^2 + X + 1 \]
## Gold Code Cross Correlation

</table>
Message Privacy

- A SS system does not provide secure message privacy unless the PN-code used is cryptographically secure.
- Maximal length and gold codes are not cryptographically secure.
JPL Ranging Codes

• Formed by modulo-2 addition of two or more maximal length sequences whose lengths are relatively prime
• The length of the JPL ranging code is the product of the lengths of the component sequences

Given maximal length sequences generated by SSRG’s of lengths 7, 10, and 13

Calculate JPL ranging code length as

\[(2^7 - 1) \times (2^{10} - 1) \times (2^{13} - 1) = 1,064,182,911 \approx 2^{30}\]
JPL Ranging Codes (cont.)

• The JPL ranging codes have 2N auto correlation values, where N is the number of component sequences
• Code synchronization is accomplished by sequentially synchronizing the component sequences
• Sequential synchronization requires searching through a maximum of \( \sum_{i=1}^{N} (2^{n_i} - 1) \) code chips vs. \( \prod_{i=1}^{N} (2^{n_i} - 1) \) for composite synchronization

Given \( N = 3, n_1 = 7, n_2 = 10, n_3 = 13 \)

Calculate \( (2^7 - 1) + (2^{10} - 1) + (2^{13} - 1) = 9,341 \)
\( (2^7 - 1) \times (2^{10} - 1) \times (2^{13} - 1) \approx 10^9 \)
Nonlinear Feedback Shift Registers

- \(2^N\) possible function
- \(2^{2^{N-1-N}}\) functions that generate on sequence of length \(2^N\)
